	DocBook to LaTeX Publishing		Ref A0
ACTION	NAME	DATE	SIGNATURE
WRITTEN BY	Benoît Guillon	03 july 2003	
REVIEWED BY	Jean-Yves Le Ruyet	03 july 2003	
APPROVED BY		03 july 2003	

REVISION HISTORY

NUMBER	DATE	DESCRIPTION	NAME
1	20/01/03	First release of the package.	B. Guillon
2	30/04/03	Changes: The script configure now checks the latex package dependencies, i.e. it checks that the packages used by the default DocBook latex style are available. The tool can be heavily customized thanks to a specification file and/or new extra options (cf. chapter 5).	B. Guillon
3	11/06/03	Changes: The xsltml library is included in the package to have a strong and consistent support of the MathML 2.0 specification. A large excerpt fo the MathML Test Suite 2.0 is now available to validate the MathML stylesheets.	B. Guillon

REVISION HISTORY

NUMBER	DATE	DESCRIPTION	NAME
4	03/07/03	Changes:	B. Guillon
		Dutch language is supported by the default latex stylesheets.	
		The subtitle element is displayed on the cover page.	
		Tables can be displayed in landscape, through the orient attribute. In addition, the table text size can be specified to be smaller by using the role attribute.	
		Hyphenation is forced in tables, so that no words can cover several cells.

Introduction

2.1 Version

This manual is for dblatex version 0.1.3.

2.2 Features

With dblatex you can:

- transform a DocBook XML/SGML book or article to pure LaTeX,
- compile the temporary LaTeX file with latex or pdflatex, to produce DVI, PostScript and PDF files,
- convert on the fly the figures included in the document,
- write complex tables,
- write several bibliographies,
- create an index,
- write mathematical equations in LaTeX,
- write mathematical equation in MathML,
- have revision bars,
- customise the output rendering with an XSL configuration file,
- use your own LaTeX style package.

2.3 Publishing Principles

Dblatex transforms a DocBook XML/SGML document to LaTeX. Once transformed into LaTeX, standard LaTeX tools are used to produce DVI, Postcript or PDF files.

2.3.1 Transforming Process

Figure 2.1 explains the process applied. It shows the tools used and the steps. The emphasized tools are provided by the package. The main script allows to use two LaTeX backend drivers:

- The "dvips" driver calls latex, and produces DVI, Postscript and at the end PDF files. The drawback is that converting to PDF can take a while.
- The "pdftex" driver calls pdflatex, to produce directly PDF files. The conversion is fast, the file size is smaller, but only PDF graphics are accepted.

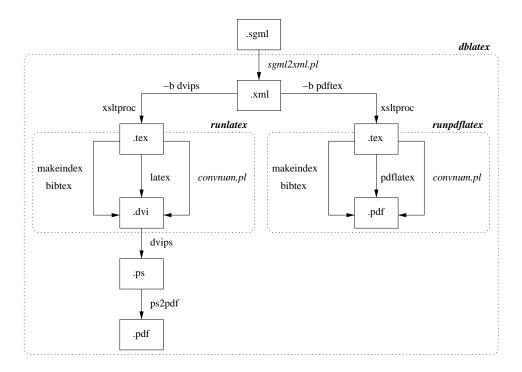

Figure 2.1: Transforming Process

2.3.2 Stylesheets

Two stylesheets are applied:

- The XSL stylesheets located under xsl/ are used to transform from XML to LaTeX. The main file is latex_book_fast.xsl, that includes the DB2LaTeX stylesheets and the other files of the directory.
- The LaTeX style package (docbook.sty) under latex/style/ is used to customize the output rendering. It includes the other files of the directory. You can also provide your own LaTeX style (cf. chapter 5).

Installing the package

3.1 Content

The package contains the following:

docs/ Contains the files of this document.

latex/ Contains all the latex stuff: LaTeX style files, logos, and scripts to compile the LaTeX output.

scripts/ Several scripts, including the main script of the package.

xsl/ XSL stylesheets, that overload or enrich the original DB2LaTeX stylesheets.

tests/ Test files.

3.2 Dependencies

To work, the following items must be available:

- An XSLT. xsltproc is the default XSLT used.
- The XML DocBook DTD.
- A recent LaTeX distribution. The configure script checks that the needed latex packages are available.
- Perl 5.x.
- GNU make.

3.3 Installation

3.3.1 Installing the dependencies

To use the package, install properly the dependencies:

- 1. Install Perl 5.x and GNU make if necessary.
- 2. Install LaTeX.
- 3. Install the XSLT. By default xsltproc is used.

- 4. Install the XML DocBook DTD.
- 5. Create a catalog file, that defines where to find the DTD. Here is an example:

```
PUBLIC "-//OASIS//DTD DocBook XML V4.1.2//EN"
    "file:///usr/local/share/xml/docbook/dtd/4.1.2/docbookx.dtd"
```

If the XML Gnome tools are available, it's a good idea to create an XML catalog by using xmlcatalog such like this:

6. Add the catalog path to the SGML_CATALOG_FILES variable:

```
export SGML_CATALOG_FILES=$SGML_CATALOG_FILES:/path/to/mycatalog
```

You can skip this step if you configure the installation with the --catalogs option.

3.3.2 Installing the tool

The steps to follow are the following:

1. Untar the ball. For a bzipped release, do as follow:

```
% bzip2 -dc dblatex-x.x.x.tar.bz2 | tar xvf -
```

For a gzipped release, do as follow:

```
% \ gunzip -c \ dblatex-x.x.x.tar.gz \mid tar \ xvf -
```

2. Call the configure script, that checks the dependencies and prepares the installation. In the example, the dblatex script is installed under /usr/local/bin and the other files are installed under /usr/local/share/dblatex. Besides, the --catalogs option tells where to find the catalog.

```
% cd dblatex-x.x.x
% ./configure --prefix=/usr/local --catalogs=/path/to/mycatalog
```

3. Install:

```
% gmake install
```

Using dblatex

4.1 Figure Inclusion

4.1.1 Presentation

The expected format of the included figures depends on the backend driver used:

dvips: EPS format is required.pdftex: PDF format is required.

In order to be able to use both backends, do not write the suffix of the file that references the figure. The suffix will be deduced from the backend used.

The figures must either already exists in the expected format, or must be able to be converted on the fly.

Example 4.1 Figure inclusion

4.1.2 Converting on the fly

The option -f fig_format allows to specify the included figures format (fig_format). Then, the tool converts the figures from the specified format to the expected one (eps or pdf).

If the specified format is unknown, no conversion is done. The supported formats are:

fig: native format of the figures produced by XFig.

eps: Encapsulated PostScript format. This format shall be specified only when using the pdftex backend.

Example 4.2 Figure conversion

The following command compiles a document that contains figures produced with XFig.

```
% dblatex -f fig mydoc.sgml
```

4.1.3 Paths Lookup

You can use the option -I "chemin1 chemin2 ..." to specify where the figures are. The given paths must be absolute. The paths are added to the doculent root path.

Example 4.3 Figures lookup

This example shows how figure lookup is done. Let's consider this document source:

And the document is compiled like this:

```
% dblatex -I "/another/path /last/case" /initial/path/document.sgml
```

The figure 1 lookup is done in the following directories, in respect of the order:

- /initial/path/rep1/rep2;
- /another/path/rep1/rep2;
- /last/case/rep1/rep2.

4.2 Creating Tables

DocBook tables can be quite complex. This is why the tool doesn't support all the possibilities. Here is what is supported:

- Columns without specified widths (colspec without colwidth attribute) have the same size.
- A table width is always equal to the page width, if at least one column doesn't contain a fixed width attribute (e.g. colwidth="12cm").
- Fixed column widths are supported (e.g. colwidth="10cm").
- Fixed column widths must be declared in centimeters ("cm").
- Proportional column widths are supported (e.g. colwidth= "5*").
- Proportional and fixed colum width together is not supported (e.g. colwidth="5*+10cm").
- The morerows attribute of a table entry (entry element) is supported.
- The orient table attribute is supported (portrait and landscape).

4.2.1 Tables without colwidth

When none of the colspec elements contains the colwidth attribute, all the columns have the same size, and the table width is fixed to the maximum available size. Several examples of these tables are given.

Column 1
left aligned
no specified width, so it takes all the page

Column 1	Column 2
left aligned	centered cell
no specified width	idem

Column 1	Column 2	Column 3	Column 4	Column 5
left aligned	left aligned	right aligned	centered cell	centered
no specified width	idem	idem	idem	idem

4.2.2 Tables with mixed colspec

A table can have colspec elements containing colwidth attribute mixed with colspec elements without colwidth. The following XML source:

```
<informaltable>
  <tgroup cols="5" colsep="1" rowsep="1" align="left">
        <colspec colname="c1"/>
        <colspec align="left" colwidth="4cm"/>
        <colspec align="right" colwidth="5cm"/>
        <colspec align="center"/>
        <colspec align="center" colwidth="3cm"/>

        ...

        </tgroup>
</informaltable>
```

is rendered like this:

Column 1	Column 2	Column 3	Column 4	Column 5
left aligned	left aligned	right aligned	centered cell	in the centre
(tgroup order)				
no specified width	4 cm column width	5 cm column width	no width	3 cm column width

4.2.3 Tables with proportional and fixed colwidth

Proportional column widths are supported. The following XML source:

```
<informaltable>
  <tgroup cols="5" colsep="1" rowsep="1" align="left">
        <colspec colname="c1" colwidth="*"/>
        <colspec align="left" colwidth="2*"/>
        <colspec align="right" colwidth="3*"/>
        <colspec align="center"/>
        <colspec align="center" colwidth="3cm"/>

        ...

        </tgroup>
        </informaltable>
```

gives this table:

Column 1	Column 2	Column 3	Column 4	Column 5
left aligned	left aligned	right aligned	centered	in the centre
(tgroup			cell	
level)				
proportion-	proportional column (2*)	proportional column (3*)	no	3 cm column width
al column			specified	
(*)			width	

4.2.4 Tables with fixed colwidths

All the columns can have fixed size, like this:

```
<informaltable>
  <tgroup cols="4" colsep="1" rowsep="1" align="left">
        <colspec colname="c1" colwidth="2cm"/>
        <colspec align="left" colwidth="2.5cm"/>
        <colspec align="right" colwidth="5cm"/>
        <colspec align="center" colwidth="3cm"/>

        ...

        </tgroup>
        </informaltable>
```

It gives the following table:

Column 1	Column 2	Column 3	Column 4
left aligned	left aligned	right aligned	centered cell
(tgroup level)			
2 cm column	2,5 cm column	5 cm column width	4 cm column width
width	width		

4.2.5 Tables with morerows

A table can contain entries that cover several lines. The following XML source contains an entry covering 4 lines:

Here is an example of table containing several entries with morerows attribute:

Column 1	Column 2	Column 3	Column 4
call on 4 lines	simple cell	cell on 2 lines	cell without morerow attribute
cell on 4 lines	cell in column 2		cell on 2 lines
	left aligned on 2	cell in line 3, column 3	cen on 2 mies
	lines	4 cm column width	last cell in column 4

4.2.6 Landscape tables

A table can be displayed in a lanscape format by using the orient attribute. The following XML source is an example.

Here is how it is displayed.

Column 1	Column 2	Column 3	Column 4	Column 5
left aligned	left aligned	right aligned	centered cell	centered
no specified width	idem	idem	idem	idem

4.2.7 Smaller tables

For big tables it can be usefull to have smaller text, so that the table is not too large or too long and it can be displayed within a page. It is possible to specify smaller table text by using the role attribute of the elements table or informaltable.

The values and the "role" dedicated to this attribute are specific to dblatex, but it is compliant with the DocBook specification because in general the role attribute purpose is never defined.

The available text size definitions supported by role are directly taken from LaTeX:

- small,
- footnotesize,
- scriptsize,
- tiny.

Here are examples for each size.

Column 1	Column 2	Column 3	Column 4	Column 5
left aligned	left aligned	right aligned	centered cell	centered
no specified width	idem	idem	idem	idem

Column 1	Column 2	Column 3	Column 4	Column 5
left aligned	left aligned	right aligned	centered cell	centered
no specified width	idem	idem	idem	idem

Column I	Column 2	Column 3	Column 4	Column 5
left aligned	left aligned	right aligned	centered cell	centered
no specified width	idem	idem	idem	idem

Column 1	Column 2	Column 3	Column 4	Column 5
left aligned	left aligned	right aligned	centered cell	centered
no specified width	idem	idem	idem	idem

4.3 Writing LaTeX mathematical equations

4.3.1 Presentation

DocBook doesn't define elements for writing mathematical equations. Only few elements exist that tell how equation should be displayed (inlined, block):

- inlineequation tells that the equation is inlined,
- informal equation tells that the equation is displayed as a block, without a title.

• equation tells that the equation is displayed as a block, with or without a title.

These tags include a graphic (graphic or mediaobject) or an alternative text equation, as shown by the example.

Example 4.4 Equation taken from TDG

```
<equation><title>Last Theorem of Fermat</title>
  <alt>x^n + y^n &ne; z^n &forall; n &ne; 2</alt>
  <graphic fileref="figures/fermat"></graphic>
</equation>
```

4.3.2 Implementation choice

The principle is to use only the alt element. If initially alt contains actually the text to print, it is chosen to use this element to embed LaTeX mathematical equations. This choice has the following advantages:

- The translation done by dblatex is really easy, since the equation is already written in LaTeX.
- LaTeX is one of the best word processor to render mathematical formulas.
- One doesn't need to write the equations in MathML.
- This method isn't specific to this tool (see the following section).

4.3.3 Compatibility

This implementation is not contradictory nor specific. In particular, the DBTeXMath proposal to extend the DSSSL stylesheets used by jade follows the same approach, and is integrated in the Norman Walsh XSL stylesheets.

4.3.4 Examples

The following examples show how to write the equations.

Example 4.5 Inlined Equation

The formula $C = \alpha + \beta Y^{\gamma} + \varepsilon$ is inlined in the paragraph. Its SGML source is:

```
<para>The formula
     <inlineequation>
          <alt>$C = \alpha + \beta Y^{\gamma} + \epsilon$</alt>
          <graphic fileref="figures/eq1"/>
          </inlineequation>
is inlined in the paragraph. Its SGML source is:</para>
```

Example 4.6 Equation in a block

The following formula:

$$C = \alpha + \beta Y^{\gamma} + \varepsilon$$

is displayed in a separate block. The SGML source is:

Example 4.7 Equation in a float

The formula Equation 4.1 below:

$$C = \alpha + \beta Y^{\gamma} + \varepsilon$$

EQUATION 4.1: Simple Formula

is displayed in a block with a title. Its SGML source is:

```
<para>The formula <xref linkend="eq-with-title"/> below:
    <equation id="eq-with-title">
    <title>Simple Formula</title>
        <alt>[C = \alpha + \beta Y^{\gamma} + \epsilon\]</alt>
        <graphic fileref="figures/eq3"/>
        </equation>
is displayed in a block with a title. Its SGML source is:</para>
```

4.4 Writing MathML equations

You can write MathML equations in a DocBook based document, by using the MathML Module for DocBook XML instead of the DocBook DTD.

dblatex now translates the MathML equations to latex by using the excellent stylesheets of the XSLT MathML Library by Vasil Yaroshevich. A large amount of tests from the W3C MathML Test Suite 2.0 is supported (657 of 712 tests). The test file used to validate the MathML stylesheets is provided in the package.

4.5 Creating an Index

An index is automatically generated if some index entries (indexterm), telling the terms to put in the index, are written in the document.

Example 4.8 Index Entry

```
<para>In this paragraph is described the function
<function>strcpy</function><indexterm><primary>strcpy</primary></indexterm>.
</para>
```

The index is put at the end of the document. It is not possible to put it somewhere else.

4.6 Writing a Bibliography

A bibliography (bibliography) can be written and put anywhere in the document. It appears as a chapter and is composed by several divisions (bibliodiv) displayed as sections.

The writer selects information that describes each bibliography entry (biblioentry), and chooses the presentation order. The titles and authors are displayed first.

Example 4.9 A Bibliography

```
<bibliography><title>Bibliography Example</title>
  <bibliodiv><title>References</title>
    <br/>biblioentry>
      <title>Document title</title>
      <author><firstname>J.</firstname><surname>Duval</surname></author>
      <pubsnumber>DEX000567325/pubsnumber>
    </biblioentry>
  </bibliodiv>
  <bibliodiv><title>White papers</title>
    <biblioentry>
      <title>Technical notes</title>
      <authorgroup>
        <author><firstname>J.</firstname><surname>Duval</surname></author>
        <author><firstname>R.</firstname><surname>Marion</surname></author>
      </authorgroup>
      <pubsnumber>DEX000704520</pubsnumber>
    </biblioentry>
  </bibliodiv>
</bibliography>
```

4.7 Document Revisions

The attribute revisionflag is usefull to identify the changes between two revisions of a document. This information is managed by dblatex, that adds revision bars in the margin of the paragraphs changed, such like in this paragraph.

Adding the revision flags can be manual, but its is tedious and error prone. The perl script diffmk by Norman Walsh can do the work for you. It works fine, but it depends on several Perl modules.

Note

The revision bars only appear when using the "dvips" driver. It seems to be a limitation of the LaTeX macros defined by the changebar package.

4.8 Publishing with dblatex

To publish your document, you just need to use the script dblatex.

4.8.1 Synopsis

```
dblatex [-t {html|tex|dvi|ps|pdf}] [-b {dvips|pdftex}] [-o output] [other options] file.{xml|sgml}
```

4.8.2 Description

The script works on an XML or SGML file and can produce LaTeX, DVI, Postscript and PDF output. By default (i.e. without option) a PDF file is produced in the same directory where the input file is, with the same base name.

4.8.3 Options

- -t: output format. By default the format is PDF.
- **-b:** backend driver to use. The available drivers are "dvips" (latex) and "pdftex" (pdflatex). By default the "dvips" driver is selected. See also Section 2.3.1.
- -f: input figures format, specified to have on the fly conversion.. See also Section 4.1.2.
- -I: additional lookup paths of the figures. See Section 4.1.3.
- -o: output filename. When not used, the input file name is used, with a suffix related to the output format.
- -d: debug mode. It only keeps the temporary directory in which dblatex actually works.
- -p: specify a configuration file. See Section 5.1.
- -S: specification file. A specification file can be used to group all the options and customizations to apply. See Section 5.5.
- -x: options to pass to the XSLT. The example below passes the options "--timing" and "--profile" to the XSLT. Using this option supposes that you know the supported XSLT options.

```
dblatex -x "--timing --profile" file.sgml
```

4.8.4 Other options

Other options are defined to customize the tool, but they should be used in exceptional cases, for test or debug purpose. These options are defined in section Section 5.5 and should normally be set through a specification file.

Customization

The transformation process (and thus the output rendering) can be heavily customized by:

- using a configuration stylesheet,
- using customized stylesheets,
- using a customized LaTeX style package.
- using a LaTeX post process script.

All these customization methods can be used independently and in exceptional cases, but it can also be combined and registered in a master configuration file, called a specification file (cf. Section 5.5) to create a new tool dedicated to your needs.

5.1 Configuration stylesheet

The PDF rendering can be customised by using an XSL configuration stylesheet. The configuration file is specified by using the option -p. The available configuration parameters are the following:

Parameter	Role	Default value
latex.hyperparam	cf. Section 5.1.1	empty

5.1.1 latex.hyperparam

This parameter gives the options to pass to the LaTeX hyperref package. No validity check is done.

For instance, the Table of Content rendering (link color, etc.) can be changed. Look at the hyperref.sty documentation to know all the hyperref options available.

Example 5.1 Configuring with latex.hyperparam

```
<?xml version='1.0' encoding="iso-8859-1"?>
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform" version='1.0'>
<!-- We want TOC links in the titles (not in the page numbers), and blue.
-->
<xsl:param name="latex.hyperparam">colorlinks,linkcolor=blue</xsl:param>
</xsl:stylesheet>
```

5.2 Customized stylesheets

If one needs to change some of the translations done by the XSL stylesheets, it is possible to provide user stylesheets to override the templates. To do this, write the stylesheets (e.g. mystyle.xsl) and include them in the configuration file such as shown by the following example.

Example 5.2 Using a customized stylesheet in a configuration file

```
<?xml version='1.0' encoding="iso-8859-1"?>
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform" version='1.0'>
<!-- Let's import our own XSL to override the default behaviour.
   -->
<xsl:import href="mystyle.xsl"/>
</xsl:stylesheet>
```

5.3 Customized LaTeX style

The actual output rendering is done by the latex style package used, and not by the XSL stylesheets whose role is only to translate to latex. Users can provide their own LaTeX style file, in respect of some rules:

- The LaTeX style package preamble must support all the options that the XSL stylesheets can pass to the package.
- Some packages must be used to make all the thing work.
- The docbook interface must be defined: the XSL stylesheets register some elements information in LaTeX commands. These commands or macro are the only ones specific to DocBook that are explicitly used by the XSL stylesheets. Other specific macros are used but are not intended to be changed by the user. These hidden macros are defined in the dbk_core latex package.

The latex style file to use is specified by using the option --style latex_style. An example of a simple LaTeX DocBook style is provided in the package.

5.3.1 Package options

Option	Role	
hyperlink, nohyperlink	Indicates if links in the document are provided or not	
article, book	The document is an article or a book	
en, fr, nl	Lang attribute of the document	

5.3.2 Needed packages

Package	Description
dbk_core	Core LaTeX definitions and macros needed for DocBook
hyperref	The package must be used since references are translated to
	\href. It is not included by default by the dbk_core package
	because the user can be interrested in customizing its call
	(specific options).

5.3.3 DocBook interface

All the latex commands beginning with DBK are related to elements under bookinfo or articleinfo.

Command	Description		
\DBKreference	mapped to pubsnumber		
\DBKsite	mapped to address		
\DBKedition	mapped to edition		
\DBKdate	mapped to date		
\DBKsubtitle	mapped to subtitle		
\DBKreleaseinfo	mapped to releaseinfo		
\DBKindexation	This command contains the othercredit information		
	translated to latex by the XSL. This command must be		
	placed where the othercredit shall appear in the document.		
\DBKindtable	This environnement must be defined by the user to render		
	the othercredit list. It can be displayed as a table, listitem,		
	description list, or anything that suits your need.		
\DBKinditem	This is an othercredit item.		
\DBKrevtable	This environnement must be defined by the user to render		
	the revhistory table. Untill now it is not really possible to		
	customize it, since it must be a table with four columns, each		
	column for a revhistory piece of information.		
float example	This float is expected to be defined, and is mapped to		
	example. It is not defined by default by the dbk_core		
	package to allow the user to define its rendering (ruled or		
	not, etc.)		
float dbequation	This float is expected to be defined, and is mapped to		
	equation. It is not defined by default by the dbk_core		
	package to allow the user to define its rendering (ruled or		
	not, etc.)		

5.4 Latex post process script

Extra user actions can be processed on the latex file produced by the XSL stylesheets or on its temporary working files produced by the latex compilation.

For instance, in the documents I write the cover page must display the number of pages of the document, but written in full letters (e.g. 23 is written "twenty three"). The latex post process script is then helpfull, and in this particular case it patches the .aux file.

The post process script is called just before the last latex compilation, and takes one parameter, the latex file compiled by the tool.

5.5 Specification file

A master configuration file, also called a specification file, can be defined to list all the customizations and options to apply. Such a file is passed by using the option -S specs.

The format of the file is the following:

- Every comment starts with a "#", and is ignored.
- The file must contain one parameter by line.
- The format of a parameter is the following:

```
<keyword>: <value>
```

- Every parameter is mapped to an option that can be passed to **dblatex**.
- An unknown parameter is silently ignored (the whole line is dropped).
- The parameters defining a path (a file or a directory) can take absolute or relative paths. A relative path must be defined from the specification file itself. For instance, a specification file under /the/spec/directory/ with a parameter describing the file ../where/this/file/is/myfile points to /the/spec/where/this/file/is/myfile.

The following table lists the supported parameters and the corresponding command line option.

Keyword	Value	Corresponding option	Description
TexInputs	Directories	texinputs	Defines extra path to add to
			TEXINPUTS
PdfInputs	Directories	pdfinputs	Defines paths containing
			PDF graphics needed to
			compile the latex file with
			pdflatex.
TexStyle	Latex package name	style	Defines the LaTeX style
			package to use.
TexPost	Script file name	texpost	Defines the LaTeX post
			process script to use.
XslParam	Parameter file name	-р	Defines the parameter file to
			use.
FigInputs	Directories	-I	Defines the extra figures
			path.
Options	Command line options	None	Lists command options to
			use by default when using
			the tool. The options
			specified by the parameter
			are directly passed to
			dblatex

Here is the specification file used for this manual.

Example 5.3 Specification file example

```
#
# Specification file example
#
TexInputs: ../latex//
PdfInputs: ../latex/graphics
TexStyle: docbook
TexPost: ../latex/example/postlatex
XslParam: myparam.xsl
Options: -b pdftex
```

5.6 Customization order

All the customization queries are translated to the corresponding command line options. Thus, using several customization methods can be unconsistent because each of them override the same option with another value.

For instance, you can specify the use of a specification file in which it is said to use a latex style (parameter TexStyle) and explicitly use the --style command line option. So, what is the behaviour?

The options order is the following:

- If a specification file is used (-S option), the options are set to the specification file parameters.
- The options explicitly passed override the specification file setting, whatever is the position of the options (i.e. before or after the -S option).
- If an option is passed several times, this is the last occurence that is used.

Example 5.4 Customization order

Let's consider the specification file containing the following parameters:

```
XslParam: file3.xsl
Options: -b pdftex
TexStyle: mystyle1
```

And now the command line:

```
dblatex -b dvips -p file1.xsl -p file2.xsl -S file.specs --style mystyle2 mydoc.sgml
```

The setting used is the following:

- "-b dvips" overrides "-b pdftex" set by the spec file.
- "-p file2.xsl" overrides "-p file1.xsl" since it is defined after, and overrides "file3.xsl" set by the spec file.
- "--style mystyle2" override "mystyle1" set by the spec file.

Thanks

Thanks to the people who contribute to the project: Jean-Yves Le Ruyet, precursory and hard-working user, Julien Ducourthial for his precious help, and all the users for their remarks to improve the product, like Vincent Hottier who asked for the embedded LaTeX equations support.
